Under the Six Sigma paradigm, control is established over the variables affecting the critical to quality characteristics. In this chapter, we first introduce some concepts of mistake-proofing strategies for process control. Then, control charts and their representation with R are explained.

Proportional control dictates $e = r - y$. From the block diagram shown, assume that r , the setpoint, is the flowrate into a tank and e is error, which is the difference between setpoint and measured process output. G_p is process transfer function; the input into the block is flow rate and output is tank level. The output as a function of the setpoint, r , is known as the closed-loop transfer function.

"p" and "np" control charts. P charts are utilized where there is a pass / fail determination on a unit inspected. The p chart will show if the proportion defective within a process changes over the sampling period (the p indicates the portion of successes). In the p chart the sample size can vary over time.

The above plot shows that new data has 3 points out of control. I explained about x-bar and R chart, but with qcc you can plot various types of control chart such as p-chart (proportion of non-confirming units), np chart (number of nonconforming units), c chart (count, nonconformities per unit) and u chart (average nonconformities per unit).

An R value of zero (on a range chart) means that the process must be in control since all sample values are equal. Range charts are used mainly with attribute data. Range charts and p-charts are both used for variable data. A p-chart is used to monitor the fraction of defectives in the output of a process.
